Unit – 1
Introduction to Cloud Computing

- Cloud computing is a technology that allows users to access computing resources—such as servers, storage, databases, software, and networking—over the internet instead of using a local computer or physical hardware.
- It enables individuals and businesses to use powerful computing services on demand, without owning or managing the underlying infrastructure.
- In cloud computing, all the resources are hosted in remote data centers operated by cloud providers like Amazon Web Services (AWS), Microsoft Azure, and Google Cloud. Users simply connect to these resources using the internet.
- Cloud computing provides scalability, flexibility, cost savings, and accessibility, making it an essential technology in today's digital world.

❖ Evolution of Cloud Computing

- Cloud computing did not appear suddenly. It evolved over several decades as computing technologies improved. Here is the step-by-step evolution:

1. 1960s – Concept of Utility Computing

- John McCarthy introduced the idea that computing could be delivered like a public utility (electricity, water).
- Mainframe computers allowed multiple users to access a central computer through time-sharing.

2**. 1970s–1980s – Virtualization Technology**

- IBM developed virtual machines (VMs), allowing one physical computer to run multiple systems.
- This concept became the foundation of cloud computing.

3. 1990s – Rise of the Internet

- The internet grew rapidly.
- Companies started offering web-based services.
- Application Service Providers (ASPs) delivered software through the web, an early form of SaaS.

4. Early 2000s – Birth of Modern Cloud

- Virtualization became more advanced and affordable.
- 2006: Amazon introduced Amazon Web Services (AWS), the first major cloud platform.
- Introduced services like S3 (storage) and EC2 (virtual servers).

5. 2010s – Expansion of Cloud Models

- Introduction of IaaS, PaaS, and SaaS.
- Microsoft Azure and Google Cloud launched.
- Businesses began migrating applications and data to the cloud.

6. 2020s – Intelligent and Hybrid Cloud

- Cloud combined with AI, Big Data, IoT, and Machine Learning.
- Hybrid cloud and multi-cloud became popular.
- Edge computing emerged for faster processing near devices.

Today – Cloud Everywhere

- Cloud powers mobile apps, streaming, e-commerce, AI tools, and enterprise systems.
- It is now essential for digital transformation worldwide.

❖ Benefits of Cloud Computing

1. **Cost Savings**
   - You don't need to buy expensive hardware or maintain servers. You only pay for what you use.

2. **Scalability**
   - Easily increase or decrease resources depending on demand.

3. **Accessibility**
   - Access data and applications from anywhere using the internet.

4. **Reliability**
   - Cloud providers offer backup, disaster recovery, and high uptime.

5. **Automatic Updates**
   - Software and security updates are handled by the cloud provider.

6. **Performance**
   - Cloud systems use fast, global data centers to improve speed and efficiency.

7. **Security**
   - Providers offer strong security measures like encryption, firewalls, and identity management.

8. **Collaboration**
   - Teams can work together in real time using cloud tools (e.g., Google Docs, Office 365).

❖ Barriers (Challenges) of Cloud Computing

1. **Internet Dependency**
   - Cloud services require a stable internet connection. Without it, access becomes slow or impossible.

2. **Security & Privacy Concerns**
   - Data stored on external servers can raise fears of unauthorized access or data breaches.

3. **Downtime**
- Even large providers may face outages, affecting access.

4. **Limited Control**
- You don't fully control the infrastructure since it's managed by the provider.

5. **Hidden Costs**
- While cheaper, unexpected usage (like storage or data transfer) can increase bills.

6. **Data Transfer Issues**
- Migrating large data to the cloud can be slow, costly, and complicated.

7. **Vendor Lock-in**
- Switching from one cloud provider to another can be difficult due to compatibility issues.

❖ **Cloud SPI Models (Service Models)**
- The term SPI stands for the three main service models of cloud computing:

1. S – SaaS (Software as a Service)
2. P – PaaS (Platform as a Service)
3. I – IaaS (Infrastructure as a Service)

These models describe what type of cloud service a user receives.

1. SaaS
- ✓ Software as a Service (SaaS) is the most user-friendly model, providing complete software applications hosted in the cloud.
- ✓ Instead of purchasing and installing software on individual devices, users can access applications over the internet.
- ✓ SaaS eliminates the need for businesses to install, maintain, or manage software themselves.

Real-World Use Cases
- ✓ Companies use Salesforce for customer relationship management (CRM), Microsoft 365 for office productivity tools, and Zoom for communication and meetings.
- ✓ All of these are SaaS products, which require no installation or maintenance by the user.

Characteristics of SaaS
- ✓ Applications are ready to use, and updates and maintenance are handled by the provider.

❖ Cloud Computing Architecture

- ✓ Cloud Computing, is one of the most demanding technologies of the current time and is giving a new shape to every organization by providing on-demand virtualized services/resources.
- ✓ Starting from small to medium and medium to large, every organization uses cloud computing services for storing information and accessing it from anywhere and at any time only with the help of the internet.
- ✓ Cloud architecture is primarily divided into two parts: the **Front End** and the **Back End**, connected via a network (usually the Internet).

1. The Front End (Client Side)

- ✓ This is what the user sees and interacts with. It includes:
  1. **User Interface:** The web browser (Chrome, Firefox) or a specialized app used to access the cloud.
  2. **Client Infrastructure:** The local hardware, such as your laptop, smartphone, or tablet.

2. The Back End (Service Side)

- ✓ Backend refers to the cloud itself which is used by the service provider.
- ✓ It contains the resources as well as manages the resources and provides security mechanisms.
- ✓ Along with this, it includes huge storage, virtual applications, virtual machines, traffic control mechanisms, deployment models, etc.

Components of Cloud Computing Architecture

- ✓ Following are the components of Cloud Computing Architecture.

1. Client Infrastructure

- ✓ Client Infrastructure is a part of the frontend component. It contains the applications and user interfaces which are required to access the cloud platform.
- ✓ In other words, it provides a GUI (Graphical User Interface) to interact with the cloud.

2. Application

- ✓ Application is a part of backend component that refers to a software or platform to which client accesses.
- ✓ Means it provides the service in backend as per the client requirement.

3. Service

- ✓ Service in backend refers to the major three types of cloud based services like SaaS, PaaS and IaaS.

- ✓ Also manages which type of service the user accesses.

4. Runtime Cloud

- ✓ Runtime cloud in backend provides the execution and Runtime platform/environment to the Virtual machine.

5. Storage

- ✓ Storage in backend provides flexible and scalable storage Service and management of stored data.

6. Infrastructure

- ✓ Cloud Infrastructure in backend refers to the hardware and software components of cloud like it includes servers, storage, network devices, virtualization software etc.

12. Analytics

- ✓ Analytics in backend service that provides analytics capabilities for data in the cloud, such as warehousing, business intelligence and machine learning.

Example = Online Store (E-Commerce Website)
Everyone is using online websites like Amazon or Flipkart for online shopping. It uses cloud computing to run its website and manage orders. When you browse and buy products, you're using the front end. In the background, cloud services keep track of what's in your cart, handle payments, and update stock. Developers use platforms like AWS Elastic Beanstalk to run the website easily.

❖ Service Level Agreements (SLAs) in Cloud Computing

- ✓ A Service Level Agreement (SLA) is a formal contract between a cloud service provider (CSP) and the customer.
- ✓ It defines the level of service the provider must deliver and the responsibilities of both parties.

Steps in SLA Lifecycle

1. Discover service provider

- ✓ This step involves identifying a service provider that can meet the needs of the organization and has the capability to provide the required service.
- ✓ This can be done through research, requesting proposals, or reaching out to vendors.

2. Define SLA

- ✓ In this step, the service level requirements are defined and agreed upon between the service provider and the organization.
- ✓ This includes defining the service level objectives, metrics (like uptime, response time), and targets that will be used to measure the performance of the service provider.

3. Establish Agreement

- ✓ After the service level requirements have been defined, an agreement is established between the organization and the service provider outlining the terms and conditions of the service.
- ✓ This agreement should include the SLA, any penalties for non-compliance, and the process for monitoring and reporting on the service level objectives.

4. Monitor SLA violation

- ✓ This step involves regularly monitoring the service level objectives to ensure that the service provider is meeting their commitments.
- ✓ If any violations are identified, they should be reported and addressed in a timely manner.

5. Terminate SLA

- ✓ If the service provider is unable to meet the service level objectives, or if the organization is not satisfied with the service provided, the SLA can be terminated.
- ✓ This can be done through mutual agreement or through the enforcement of penalties for non-compliance.

6. **Enforce penalties for SLA Violation**

- ✓ If the service provider is found to be in violation of the SLA, penalties can be imposed as outlined in the agreement.
- ✓ These penalties can include financial penalties, reduced service level objectives, or termination of the agreement.

Advantages of SLA

1. **Improved communication**

- ✓ A better framework for communication between the service provider and the client is established through SLAs, which explicitly outline the degree of service that a customer may anticipate.
- ✓ This can make sure that everyone is talking about the same things when it comes to service expectations.

2. **Increased accountability**

- ✓ SLAs give customers a way to hold service providers accountable if their services fall short of the agreed-upon standard.
- ✓ They also hold service providers responsible for delivering a specific level of service.

3. **Better alignment with business goals**

- ✓ SLAs make sure that the service being given is in line with the goals of the client by laying down the performance goals and service level requirements that the service provider must satisfy.

4. **Reduced downtime**

- ✓ SLAs can help to limit the effects of service disruptions by creating explicit protocols for issue management and resolution.

5. **Better cost management**

- ✓ By specifying the level of service that the customer can anticipate and providing a way to track and evaluate performance, SLAs can help to limit costs.
- ✓ Making sure the consumer is getting the best value for their money can be made easier by doing this.

Disadvantages of SLA

1. **Complexity**

- ✓ SLAs can be complex to create and maintain, and may require significant resources to implement and enforce.

2. **Rigidity**

- ✓ SLAs can be rigid and may not be flexible enough to accommodate changing business needs or service requirements.

3. **Limited service options**

- ✓ SLAs can limit the service options available to the customer, as the service provider may only be able to offer the specific services outlined in the agreement.

4. **Misaligned incentives**

- ✓ SLAs may misalign incentives between the service provider and the customer, as the provider may focus on meeting the agreed-upon service levels rather than on providing the best service possible.

5. **Limited liability**

SLAs are not legal binding contracts and often limited the liability of the service provider in case of service failure.

❖ **Types Of Service Level Agreements (SLAs)**

- ✓ An SLA (Service Level Agreement) defines the level of service expected from a cloud service provider.

1. **Customer-Based SLA**

- ✓ An SLA customized for a specific customer.
- ✓ Designed for one individual customer

2. **Service-Based SLA**

- ✓ An SLA that applies to all customers using the same service.
- ✓ Same SLA for all users
- ✓ Covers one specific service
- ✓ Simple and standardized
- ✓ Easier for providers to manage
- ✓ Limited customization
- ✓ Example: SLA for cloud storage service (99.9% availability)

3. **Multi-Level SLA**

- ✓ An SLA structured into multiple levels to address different user needs.
- ✓ Combination of customer-based and service-based SLAs
- ✓ Contains multiple SLA layers
- ✓ Levels include:
    - ➢ Corporate level
    - ➢ Customer level
    - ➢ Service level

- ✓ Flexible and scalable
- ✓ Supports different service tiers

❖ Technical Considerations for Migration to the Cloud

Migrating to the cloud involves moving applications, databases, and workloads from on-premise infrastructure to a cloud environment (AWS, Azure, GCP, etc.). Successful migration requires careful technical evaluation and planning.

Key Technical Considerations

1. Application Architecture
- Evaluate whether applications are **monolithic or microservices-based**
- Modify applications to be **stateless**
- Ensure cloud-native compatibility

2. **Data Migration**
- Assess data size, type, and sensitivity
- Choose appropriate data transfer methods
- Ensure data integrity and consistency

3. **Security and Compliance**
- Implement Identity and Access Management (IAM)
- Encrypt data during transit and at rest
- Ensure compliance with legal and regulatory standards

4. **Network and Connectivity**
- Evaluate network bandwidth and latency
- Use VPN or dedicated connections
- Ensure high availability and redundancy

5. **Performance and Scalability**
- Design for auto-scaling
- Implement load balancing
- Optimize resource usage

6. **Cost and Billing Management**
- Understand pricing models
- Monitor resource consumption
- Avoid unexpected costs

Cloud Migration Strategies (6 R's)

1. **Rehost** – Move applications without changes
2. **Refactor** – Modify applications for cloud optimization
3. **Replatform** – Minor changes to use cloud features
4. **Repurchase** – Replace with SaaS solutions
5. **Retire** – Eliminate obsolete applications
6. **Retain** – Keep applications on-premise

❖ Cloud Services

3.1 Cloud Service Models

1. Infrastructure as a Service (IaaS)

➢ Provides **virtualized computing resources** such as servers, storage, and networks.

Characteristics:

✓ High flexibility
✓ User manages OS and applications
✓ Pay-as-you-use model

Examples:

✓ Amazon Web Services
✓ Microsoft Azure
✓ Google Cloud Platform

2. Platform as a Service (PaaS)

➢ Provides a complete **application development and deployment environment**.

Characteristics:

✓ No infrastructure management
✓ Faster development
✓ Built-in scalability

3. Software as a Service (SaaS)

➢ Delivers **ready-to-use software applications** over the internet.

Characteristics:

✓ Web-based access
✓ Subscription pricing
✓ Automatic updates

Cloud Deployment Models

- **Public Cloud** – Services offered to the public over the internet
- **Private Cloud** – Dedicated cloud for a single organization
- **Hybrid Cloud** – Combination of public and private cloud
- **Community Cloud** – Shared by organizations with common requirements
